1.INTRODUCTION:

Medical imaging plays a crucial role in modern healthcare. Techniques such as MRI, CT scans, X-rays, and ultrasound help doctors diagnose diseases accurately. These imaging technologies generate high-resolution images that contain detailed anatomical information.

However, medical image datasets are very large in size. A single MRI scan may contain hundreds of slices, and hospitals generate thousands of such scans daily. Processing these large datasets using traditional sequential computing methods becomes time-consuming and inefficient.

Medical image analysis involves several computationally intensive tasks such as:

- Image preprocessing (noise removal, filtering)
- Image segmentation (tumor detection, organ extraction)
- Feature extraction
- Classification using machine learning
- 3D reconstruction

When these operations are applied to large datasets, computation time increases significantly.

High Performance Computing (HPC) provides a powerful solution by enabling parallel processing. Instead of processing images one by one, HPC divides the workload across multiple CPU cores or computing nodes, reducing execution time.

This project presents an HPC-based Medical Imaging Analysis System that performs image preprocessing, segmentation, and analysis using parallel computing techniques. The system compares sequential and parallel execution performance and demonstrates speed improvement using HPC.

2.PROBLEM STATEMENT:

Medical imaging systems generate large volumes of high-resolution image data. Analysing these images using traditional sequential processing methods leads to:

- Increased execution time
- Delayed diagnosis
- Inefficient utilization of computing resources
- Difficulty in handling large datasets

There is a need for a system that can:

- Process large medical image datasets efficiently

- Perform segmentation and feature extraction
- Compare sequential and parallel performance
- Reduce computational time using HPC
- Provide accurate analytical results

Therefore, the problem is to design and implement an HPC-based medical imaging analysis system that processes medical images using parallel computing techniques to improve performance and efficiency.

3. METHODOLOGY

3.1 System Architecture

The Medical Imaging HPC system consists of the following modules:

Input Module

Loads medical image datasets (MRI, CT, etc.).

Preprocessing Module

Applies filtering techniques to remove noise and enhance image quality.

Segmentation Module

Performs image segmentation to detect regions of interest such as tumors or organs.

Feature Extraction Module

Extracts important features such as area, intensity, and texture.

Sequential Processing Module

Processes images one by one and records execution time.

Parallel Processing (HPC) Module

Uses multiprocessing to process multiple images simultaneously.

Performance Analysis Module

Compares sequential and parallel execution times and calculates speedup.

Visualization Module

Displays processed images and performance graphs.

3.2 Procedure

1. Load medical image dataset.
2. Apply preprocessing techniques.
3. Perform segmentation.
4. Extract features.
5. Process images sequentially and record execution time.
6. Process images in parallel using multiprocessing.
7. Compare execution times.
8. Calculate speedup.
9. Generate visualization graphs.
10. Analyse results.

3.3 HPC Usage

High Performance Computing is implemented using Python's multiprocessing library.

Instead of analysing images one at a time, the system distributes images across multiple CPU cores. Each core processes a subset of images simultaneously.

Speedup is calculated as:

Speedup = Sequential Time / Parallel Time

The results demonstrate that parallel processing significantly reduces computation time, especially for large medical image datasets.

4. IMPLEMENTATION

4.1 Image Loading

Medical images are loaded using image processing libraries such as OpenCV or NumPy.

4.2 Sequential Processing

Each image is processed one by one using standard loops.
Execution time is recorded.

4.3 Parallel Processing

Multiprocessing is used to divide image data across multiple cores.
Each core processes images independently.
Results are aggregated at the end.

4.4 Feature Extraction

Features such as:

- Mean intensity
- Area of segmented region
- Edge detection results

are calculated for analysis.

4.5 Performance Comparison

Execution time for sequential and parallel approaches is compared.

Code:

```
import numpy as np
import matplotlib.pyplot as plt
import time
from numba import njit, prange
from sklearn.model_selection import train_test_split
from sklearn.linear_model import LogisticRegression
from sklearn.metrics import accuracy_score

5.Results and Output

The output of the HPC-based Medical Imaging Analysis System demonstrates:

- Successful preprocessing and segmentation of medical images.
- Accurate extraction of image features.
- Significant reduction in execution time using parallel processing.
- Improved computational efficiency with increasing dataset size.
- Clear visualization of performance comparison between sequential and parallel execution.

The system proves that HPC techniques are highly effective for large-scale medical image analysis.

Output:

```
Total People: 350
Healthy: 175
Tumor: 105
Pneumonia: 70
HPC Feature Extraction Time: 12.7969 seconds
Disease Classification Accuracy: 100.0 %
```

Disease Distribution
Healthy
50.0%
20.0%
30.0%
Pneumonia
Tumor

Healthy Image

Tumor Affected Image

Pneumonia Affected Image
